

Coot

Fulica atra

Category A

Breeding resident and winter visitor.

Widespread across much of Europe eastwards across southern Siberia to the Pacific, and south to Arabia, India and Australia. In warm and temperate regions, present all year (though individuals not necessarily resident), but mainly migratory in northern and especially eastern Europe under the influence of the continental climate, with small numbers even reaching sub-Saharan Africa (Snow & Perrins, 1998).

A common and widespread resident breeding species and winter visitor in Kent (KOS, 2020).

Coot at Princes Parade (Nigel Webster)

Breeding distribution

Figure 1 shows the breeding distribution by tetrad based on the results of the 2007-13 BTO/KOS atlas fieldwork.

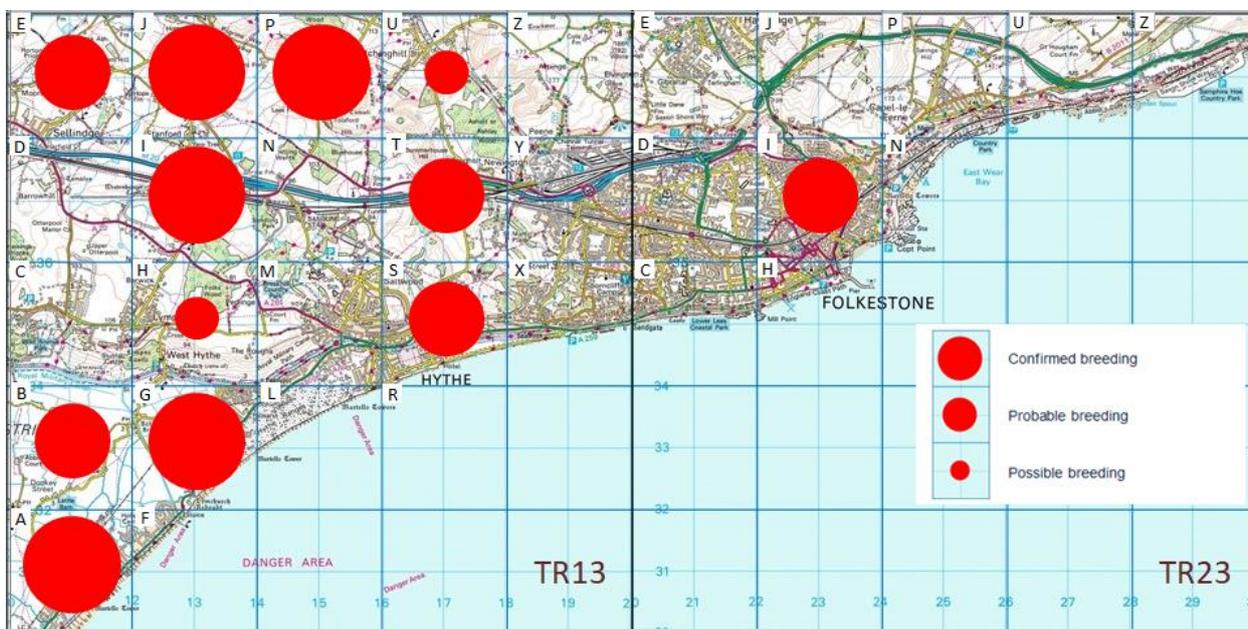

Figure 1: Breeding distribution of Coot at Folkestone and Hythe by tetrad (2007-13 BTO/KOS Atlas)

Breeding was confirmed in five tetrads, with probable breeding in five more and possible breeding in two others. The table below shows how this compares to previous atlases (Taylor *et al* 1981, Henderson & Hodge 1998). The confirmed and probable breeding categories have been combined to account for differing definitions of these in the first atlas.

Breeding atlases	1967 – 1973		1988 - 1994		2007 - 2013	
Possible	0	(0%)	3	(10%)	2	(6%)
Probable/Confirmed	1	(3%)	1	(3%)	10	(32%)
Total	1	(3%)	4	(13%)	12	(39%)

Coots have frequented the Nickolls Quarry area since at least November 1950 and up to six pairs nested there in the early 1950s, with two to three pairs since. The only breeding record in the first atlas was undoubtedly at this site (in TR13 G), which is the largest local waterbody, with Taylor *et al* noting that “the Coot... usually requires at least half a hectare of open water and dense vegetation for nesting”.

Henderson & Hodge, in reviewing the results of the second county atlas, concluded that there were “all the indications of an expansion of range since the first atlas and, although some of this may be due to better coverage, a good deal of it may be genuine. Some of the spread has been on to new gravel pits and reservoirs but elsewhere it appears that the species has colonised existing water bodies including relatively small ponds and dykes. This could be the result of an increasing population spilling over from the preferred larger wetlands as they reach capacity”. TR13 G was again occupied (presumably at Nickolls Quarry) and it had also spread to TR13 B (presumably at one of the sewers on Romney Marsh), TR13 E (presumably at Cock Ash Lake or Horton Priory) and TR13 T (presumably at Beachborough Lakes).

Clements *et al* (2015) commented on a further expansion in the third atlas, with an increase in occupied tetrads of 33%, remarking that “it seems likely that the spread into more marginal habitat noted in the second Kent atlas has continued. The establishment of more small fishing lakes on farmland in the county will have helped this spread”. They also remarked that the increase showed some correlation to the BBS trend increase in south-east England of 28% between 1995 and 2012.

It is currently quite well-distributed within TR13 but the only nesting site within TR23 is Radnor Park in Folkestone.

Non-breeding distribution

Figure 2 shows the distribution of all records of Coot by tetrad, with records in 19 tetrads (61%).

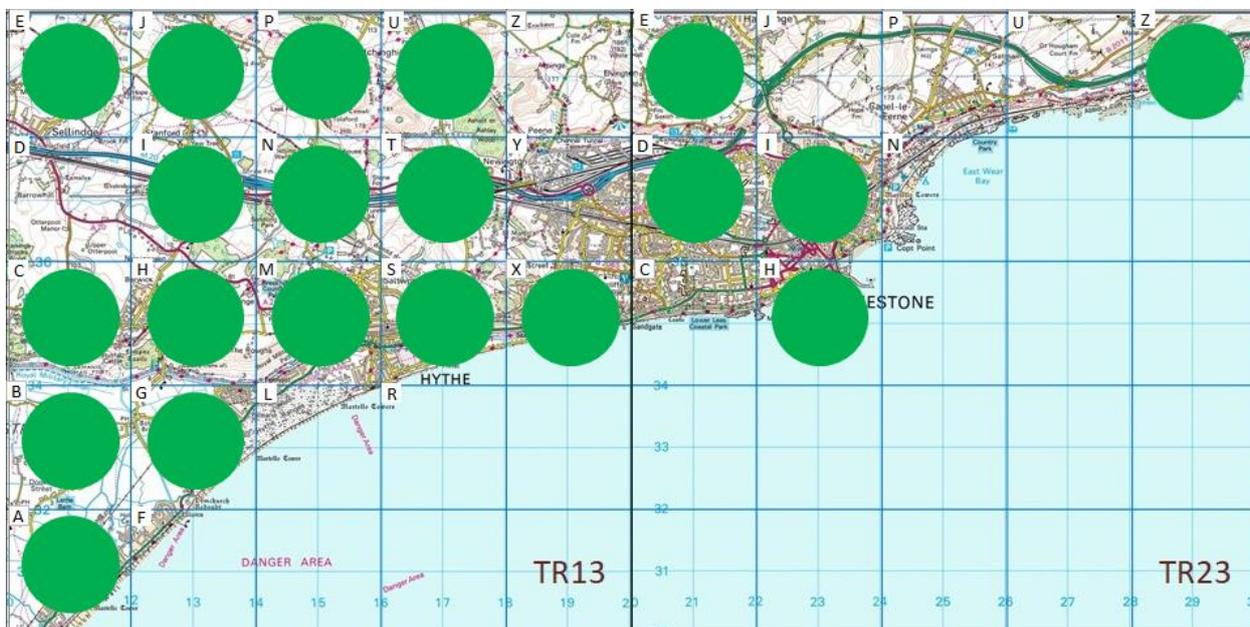

Figure 2: Distribution of all Coot records at Folkestone and Hythe by tetrad

The first significant winter numbers at Nickolls Quarry were recorded in the 1957/58 winter, when there was a peak of 64 on the 31st January 1958, whilst the next two winters produced peaks of 60 on the 15th February 1959 and 70 on the 7th February 1960. The 1961/62 winter saw even greater numbers, with a minimum of 130 present on the 5th February 1962, whilst 80 were still present on the relatively late date of 25th March.

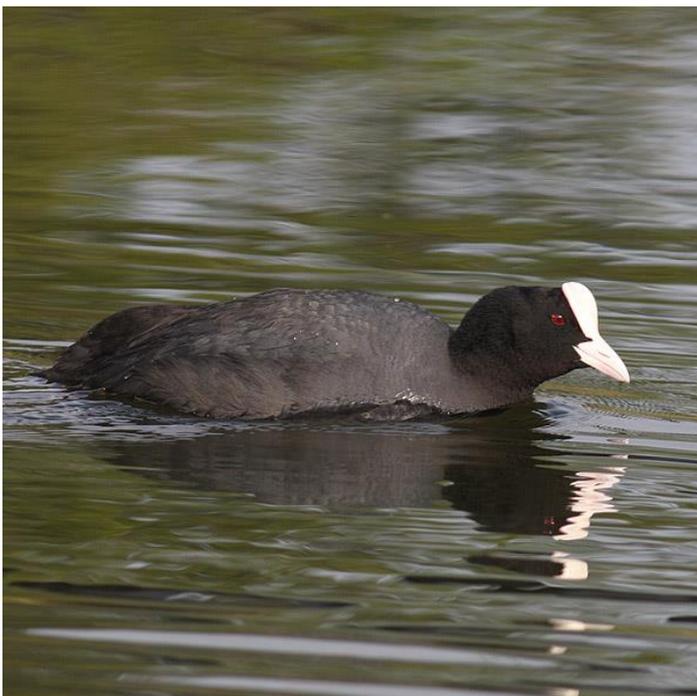

Subsequent counts at this site included 87 on the 28th December 1969, up to 200 in January/February 1970, 180 on the 23rd January 1979, c.200 on the 14th January 1982 (with 120 still present on the 21st February) and “well over 100” in February 1985. In the 1990s there were further counts there of 115 on the 3rd March 1993 and 119 on the 28th December 1996, with 107 on the 25th December 2010.

Large numbers were typically associated with severe weather. There have been no three-figure counts since 2010, which may be due to a succession of mild winters, but increased disturbance and habitat degradation associated with development works are also likely to have had an impact. The largest count there in recent years was 23 on the 1st January 2020.

Other sites that have produced double-figure counts are the Royal Military Canal between Hythe and Palmersh (where there were 22 on the 22nd November 1959), the lake near Rose Cottage on Burmarsh Road (where there was a peak of 28 on the 16th December 2009), West Hythe (with a peak of 10 on the 31st January 2011), the Willop Basin (with a peak of 12 on the 24th November 2018), Beachborough Lakes (with a peak of 14 on the 27th March 2019) and Cock Ash Lake (with a peak of 15 on the 7th December 2019).

Apart from a breeding pair at Radnor Park it is an exceptionally rare bird in TR23, where there have been just five other records as follows:

- One in Folkestone Harbour (TR23 H/I) on the 9th January 1993
- Up to three in Folkestone Harbour (TR23 H/I) between the 3rd and 8th January 1997
- One on the main pond at Samphire Hoe (TR23 Z) on the 13th July 2001
- One at Cherry Garden reservoirs (TR23 D/E) on 25th January 2010
- Two in Folkestone Harbour (TR23 H/I) between the 10th January and 18th February 2011
